

Page 1, lines 13-20

#2  
As an alternative to private line access, communications service providers such as AT&T also offer virtual circuit access allowing several customers to logically share a single circuit, thus reducing costs. Such shared circuits, typically referred to as Permanent Virtual Circuits, allow communication service providers to guarantee customer traffic flows that are distinguishable from each other, are secure, and allow customers to enjoy different service features. An example of such a technique for offering such shared service is disclosed in U.S. Patent 6,081,524, assigned to AT&T.

Page 2, lines 8-20

A  
Briefly, in accordance with a preferred embodiment, a method is provided for routing data in an Ethernet protocol network having a plurality of platforms, each serving one or more customers. A first platform receives at least one frame from a sending site (e.g., a first customer's premises) that is destined for a receiving site (e.g., another premises belonging to the same or a different customer.) After receiving the frame, the first platform overwrites a portion of the frame with a **customer descriptor** that specifically identifies the sending customer. In practice, the first platform may overwrite a Virtual Local Area Network (VLAN) field that is typically employed by the sending customer for the purposes of routing data among various VLANs at the sending premises. Rather than overwrite the VLAN field in the frame, the first platform could overwrite another field, such as the source address field, or could even employ a "shim" header containing the customer descriptor. All further use of the term **customer descriptor** implies that any of the above or similar techniques could be used.

Page 2, lines 21-28, page 3, lines 1-2

A4  
After overwriting the frame with the customer descriptor, the sending platform routes the frame onto the MAN for routing among the other platforms, thereby sharing trunk bandwidth and other resources, but logically distinct from other customers' traffic with different customer descriptors. A destination address in the frame directs the frame to its corresponding endpoint. Upon receipt of the frame, the receiving platform uses the customer descriptor to segregate the frame for delivery to the proper destination, especially in the event where different customers served by the same platform use overlapping addressing plans. Thus, the customer descriptor in each frame advantageously enables the receiving platform to distinguish between different customers served by that platform.

Page 3, lines 3-6

A5  
For traffic with a destination beyond the MAN, this method provides a convenient and efficient way to map the customer descriptor to similar identifiers in a Wide Area Network (WAN), such as a Permanent Virtual Circuit (PVC), a Virtual Private Network (VPN), or an MPLS Label Switched Circuit.

Page 3, lines 7-13

A6  
Overwriting each frame with the customer descriptor thus affords the ability to logically segregate traffic on the Ethernet MAN to provide Virtual Private Network (VPN) services of the type offered only on more expensive Frame Relay and ATM networks. Moreover, the customer descriptor used to tag each frame can advantageously include Quality of Service (QoS) information, allowing the sender to specify different QoS levels for different traffic types, based on the Service Level Agreement (SLA) between the customer and the communications service provider.

Page 4, lines 4-10

A 11  
FIGURE 1 depicts an Ethernet Protocol Metropolitan Area Network (MAN) 10 comprised of a plurality of Multi-Service Platforms (MSPs)  $12_1$ - $12_n$  where  $n$  is an integer, each MSP taking the form of an Ethernet switch or the like. In the illustrated embodiment  $n=4$ , although the network 10 could include a smaller or larger number of MSPs. A fiber ring or SONET ring infrastructure 14 connects the platforms  $12_1$ - $12_4$  in daisy-chain fashion allowing each MSP to statistically multiplex information onto, and to statistically de-multiplex information off the ring infrastructure 14.

Page 4, lines 11-21

A 1 2  
Each of MSPs  $12_1$ - $12_3$  serves at least one, and in some instances, a plurality of premises 16 belonging to one or more customers. In the illustrated embodiment of FIG. 1, the MSP  $12_1$  serves a single customer premises  $16_1$  belonging to customer 1 whereas, the MSP  $12_2$  serves premises  $16_2$  and  $16_3$  belonging to customers 2 and 3, respectively. The MSP  $12_3$  serves a single premises  $16_4$  that belongs to customer 3. The MSPs  $12_1$ - $12_3$  are linked to their corresponding premises via 10, 100 or 1000 MB links 19. The MSP  $12_4$  bears the legend "CO MSP" because it serves as a central office to route traffic from the MAN 10 to a Provider Edge Router (PER) 18 for delivery to other networks, such as Frame Relay, ATM, MPLS networks or the Internet as discussed hereinafter. By the same token, the PER 18 can route traffic from such other networks onto the MAN 10 via the CO MSP  $12_4$ .

page 4, lines 20-29

A 13 cont.  
The traffic routed onto and off of the MAN 10 by each MSP takes the form of one or more frames 20 depicted in FIG. 2. Heretofore, traffic routed onto the MAN 10 from a particular customer's premises was combined with other customers' traffic with no

A13  
Concl

logical separation, thus raising security concerns. Moreover, since all customers' traffic share the same bandwidth, difficulties existed in prior art Ethernet MANs in regulating the traffic from each customer's premises, and in affording different customers different Quality of Service (QoS) levels in accordance with individual Service Level Agreements.

Page 5, lines 1-8

A14

These difficulties are overcome in accordance with the present principles by "tagging" each frame 20 routed onto the MAN 10 at a particular MSP, say MSP 12<sub>3</sub>, with a customer descriptor 22' (best seen in FIG. 2) that identifies the customer sending that frame. As discussed in greater detail below, each MSP receiving a frame 20 on the fiber ring infrastructure 14 uses the customer descriptor 22' in that frame to maintain distinct routing and addressing tables that are assigned to each customer served by that MSP. This permits each customer to use its own addressing plan without fear of overlap with other customers, as the customers are all maintained as logically separate.

Page 5, lines 9-15

A15

FIGURE 2 depicts the structure of an exemplary Ethernet protocol frame 20 specified by Ethernet Standard 802.1Q. Among the blocks of bytes within each frame 20 is a Virtual Local Area Network (VLAN) Identifier 22 comprised of sixteen bits. In practice, the VLAN identifier 22, in conjunction with a VLAN flag 23 within the frame, facilitates routing of the frame within a customer's premises to a particular VLAN. However, the VLAN identifier 22 has no influence on routing of the frame 20 after receipt at a MSP.

Page 5, lines 16-28

A16  
In accordance with the present principles, the prior disadvantages associated with conventional Ethernet networks, namely the lack of security and inability to regulate QoS levels, are overcome by overwriting the VLAN identifier 22 in each frame 20 with the customer descriptor maintained by the service provider. Overwriting the VLAN identifier 22 of FIG. 2 of each frame 20 with the customer descriptor 22' serves to "tag" that frame with the identity of its sending customer, thus affording each MSP in the MAN 10 the ability to route those frames only among the premises belonging to that same sending customer. Such tagging affords the operator of the MAN 10 the ability to provide security in connection with frames transmitted across the network, since frames with customer ID A would not be delivered to any premises of customer with ID B. As an example, two or more customers served by a single MSP may use overlapping IP addressing schemes. In the absence of any other identifier, the MSP receiving frames with overlapping IP addresses lacks the ability to assure accurate delivery.

Page 5, lines 29-31, Page 6, lines 1-3

A17  
In the illustrated embodiment depicted in FIG. 2, each MSP of Fig. 1 tags each outgoing frame 20 by overwriting the VLAN identifier 22 with the customer descriptor 22'. However, tagging could occur in other ways, rather than overwriting the VLAN identifier 22. For example, the source address block 25 within the frame 20 could be overwritten with the customer descriptor 22'. Alternatively, the data field 21 could include a shim header comprising the customer descriptor 22'.

Page 6, lines 4-15

A18 cont.  
The tagging of each frame 20 with the customer descriptor 22' affords several distinct advantages in connection with routing of the frames through the MAN 10. First,

A 19  
Cont

as discussed above, the tagging affords each recipient MSP the ability to distinguish traffic destined for customers with overlapping address schemes, and thus allows for segregating traffic on the MAN 10. Further, tagging each frame 20 with the customer descriptor 22' enables mapping of the frames from a MAN 100 depicted in FIG 3 to corresponding one of a plurality of customer Virtual Private Networks 26<sub>1</sub>-26<sub>3</sub>, within an MPLS network 28. As seen in FIG. 3, an MSP 120<sub>2</sub> within the MAN 100 receives traffic from premises 160<sub>1</sub>, 160<sub>2</sub>, and 160<sub>3</sub> belonging to customer 1, customer 2 and customer 3, respectively, which enjoy separate physical links to the MSP. Upon receipt of each frame from a particular customer, the MSP 120<sub>2</sub> overwrites that frame with the customer descriptor 22' corresponding to the sending customer.

Page 6, lines 16-22

A 19

After tagging each frame, the MSP 120<sub>2</sub> statistically multiplexes the frames onto the fiber ring infrastructure 14 for transmission to a CO MSP 120<sub>4</sub> for receipt at a destination PER 180 that serves the MPLS network 28 within which are customer Virtual Private Networks 26<sub>1</sub>-26<sub>3</sub>. Using the customer descriptor 22' in each frame, the PER 180 maps the frame to the corresponding VPN identifier associated with a particular one of customer Virtual Private Networks 26<sub>1</sub>-26<sub>3</sub> to properly route each frame to its intended destination.

Page 6, lines 23-31, page 7, lines 1-2

A 20  
Cont

The tagging scheme of the present invention also affords the ability to route frames with different QoS levels within a MAN 1000 depicted in FIG 4. As seen in FIG. 4, an MSP 1200<sub>2</sub> within the MAN 1000 receives traffic from premises 1600<sub>2</sub>, and 1600<sub>3</sub> belonging to customer 2 and customer 3, respectively, which enjoy separate physical links to the MSP, allowing each to send frames into the MAN. In the illustrated embodiment of FIG. 4, the frames originating from the premise 1600<sub>2</sub> may

Serial No.: 09/792,360

Art Unit 2661

IDS 2000-0660

#20  
cont.

contain either voice or data and have a corresponding QoS level associated with each type of frame. Upon receiving such frames, the MSP 1200<sub>2</sub> overwrites the frame with the customer descriptor 22' corresponding to the particular customer sending the frame. The customer descriptor 22' will not only contain the identity of the sending customer, but the corresponding QoS level associated with that frame.

page 7, lines 3-10

A21

After tagging each frame, the MSP 1200<sub>2</sub> statistically multiplexes the frames onto the fiber ring infrastructure 14 for transmission to a CO MSP 1200<sub>4</sub> for receipt at a destination PER 1800 that serves an MPLS network 280 within which are customer Virtual Private Networks 260<sub>2</sub> and 260<sub>3</sub>. Using the customer descriptor 22' in each frame, the PER 1800 of FIG. 4 maps the frame to the corresponding customer VPN to properly route each frame to its intended customer VPN. Further, the PER 1800 of FIG. 4 also maps the QoS level specified in the customer descriptor in the frame to assure that the appropriate quality of service level is applied to the particular frame.

Page 7, lines 11-27

#21  
cont.

In the above-described embodiments, the frames of customer traffic have been assumed to comprise IP packets that terminate on a router (i.e., Provider Edge Routers 18, 180 and 1800) and that the VPNs employ MPLS-BGP protocols. However, some customers may require multi-protocol support, or may otherwise require conventional PVCs so that the traffic streams must be mapped into Frame Relay or ATM PVCs as depicted in FIG. 5, which illustrates a portion of a MAN 10000 having a CO MSP 12000<sub>4</sub> serving an ATM switch 30 that receives traffic from the MAN. As seen in FIG. 5, each of premises 16000<sub>1</sub>, 16000<sub>2</sub> and 16000<sub>3</sub> belonging to customer 1, customer 2 and customer 3, respectively, may send frames for receipt at MSP 12000<sub>2</sub> in the MAN 10000. The MSP 12000<sub>2</sub> tags each frame with the corresponding customer descriptor prior to

*A 22  
Concl.*

statistically multiplexing the data for transmission on the fiber ring infrastructure 14 to the CO MSP 12000<sub>4</sub> for receipt at the ATM switch 30. The ATM switch 30 then maps each frame to the appropriate PVC in accordance with the customer descriptor 22' in the frame in a manner similar to the mapping described with respect to FIG. 3. Thus, the ATM switch 30 could map the frame to one of Frame Relay recipients' 32<sub>1</sub>, 32<sub>2</sub>, or 32<sub>3</sub>, ATM recipients 32<sub>4</sub> or 32<sub>5</sub>, or IMA (Inverse Multiplexing over ATM) recipient 32<sub>6</sub>.

*A 23*

FIG. 6 depicts a portion of a MAN network 100000 that routes frames onto separate MPLS tunnels 40<sub>1</sub>-40<sub>3</sub> (each emulating a private line 32 in an MPLS network 28000) in accordance with the customer descriptor 22' written into each frame by a MSP 120000<sub>2</sub> in the MAN. Each of customer premises 160000<sub>1</sub>, 160000<sub>2</sub> and 160000<sub>3</sub> depicted in FIG. 6 sends information frames for receipt at MSP 120000<sub>2</sub>. The MSP 120000<sub>2</sub> tags each frame with the customer descriptor prior to statistically multiplexing the data for transmission on the fiber ring infrastructure 14 for delivery to a CO MSP 120000<sub>4</sub> that serves a PER 18000. The PER 18000 translates (maps) the customer descriptors written onto the frames by the MSP 120000<sub>2</sub> into the MPLS tunnels 40<sub>1</sub>-40<sub>3</sub> to enable the PER to route the traffic to the intended customer.
